

HQ 17

(a) // $x[1 \dots n]$ is an array of bits, that will be used to in the following operations.

(i) def Init(n):

for $i = 1$ to n
 $x[i] = 0$

(ii) def Set(i):

if ($i \geq 1$ & & $i \leq n$)
 $x[i] = 1$

(iii) ~~def IsSet(i):~~
~~return $x[i]$~~

def IsSet(i):
 if ($i \geq 1$ & & $i \leq n$)
 return $x[i]$

(iv) def NextUnset(i):

for $k = i$ to n
 if ($x[k] == 0$)
 return k

time complexity of the above operations —

(i) $\Theta(n)$

// given n , the for loop will run for all the n bits and set it to value 0

(ii) $\Theta(1)$

// constant operation

(iii) $\Theta(1)$

// constant operation

(iv) $O(n)$

// we will return k as soon as we find $x[k] = 0$ and the for loop will terminate

⑥ (i) def Init(i):
for ~~int~~ i = 1 to n
makeSet(i)
i.val = 0
i.ptr = i

(ii) def Set(i):
if ($i \geq 1$ & & $i \leq n-1$ & & $i.val == 0$)
a) temp = find(i+1).ptr
b) i.val = 1
c) union(i+1, i)
d) find(i).ptr = temp.

(iii) def ISet(i):
if ($i \geq 1$ & & $i \leq n$)
return i.val

(iv) def NextUnset(i):
if ($i \geq 1$ & & $i \leq n$)
return find(i).ptr

In the disjoint set, each element will correspond to the index of the array of bits $x[1 \dots n]$. Each disjoint set element is an object which has 2 fields named `.val` and ~~`.ptr`~~ which stores the value of the element corresponding to the array and `.ptr` which stores ~~the~~ / points to the next element which has a value of 0; including itself i.e. if an element has 0 value `.ptr` will point to itself.

The intuition behind the approach is, opts will always point to the element which has a value of 0 including itself i.e. if i is an element with value 0 then its opt will point to itself and if not then its opt will point to some greater index than i s.t. ~~its value~~ that index's value is 0. Now whenever we are performing a $\text{union}()$ we are doing it ^{when an element's value is set to 1 and} with the next element of i i.e. we always do a union of i & $i+1$, thus ensuring $(i+1)$'s leader.opt will always give me the index of element with value 0 ^{and which will be greater than} ~~so~~ whenever a new element is combined in a set we make use of the above ~~info~~ ~~&~~ fact and store that element with value 0 in the leader.opt of the newly formed set. So all the element with value set as 1 are combined together ~~with an element of value~~ ~~& s.t. the leader of this set has the~~ points to the ^{next higher index of equal} ~~element~~ with value 0.

First when $\text{Init}(i)$ is called we make singleton sets and also we store the value of such elements as 0 (as per the definition of $\text{Init}()$) and point the ptr pointer to itself cause as per the ptr pointer definition above, we are marking / pointing ptr to the next element which has 0 value including it self. These operations we do in (b) (i) as written above.

Now ~~when~~ when $\text{Set}(i)$ is called, after checking the array ~~lower~~ size bounds, we first store the $(i+1)$'s leader - ptr in a variable. We do so because $i+1 > i$ and even if $(i+1)$ element is in a ~~set~~ singleton set or not its leader is $\text{find}(i+1)$. ~~with~~ ptr will always point to the next element having value 0 including itself. Now we do a union of $i+1$ and i element, thus ensuring contiguous bits of 1 are combined in one set. But again in this newly formed set, the leader ~~might~~ must point to the ~~next~~ ^{with higher index} element with value = 0.

Thus we take $\text{find}(i) \cdot \text{ptr}$ which is ~~find~~
 $\text{leader}(i) \cdot \text{ptr}$ & store temp in this. temp will
always ensure that on index of higher value is
stored as ~~temp itself was st~~ $= \text{find}(i+1) \cdot \text{ptr}$
where $\cdot \text{ptr}$ can point to element itself or any
element of a greater index. We do these operations
in (b) (ii)

In (b) (iii) after checking the array size bounds,
Is $\text{set}()$ simply returns the value stored in
the i th element, where i is the passed parameter.

When $\text{NextUnset}(i)$ is called, we simply check
the array ^{size} bounds and return $\text{find}(i) \cdot \text{ptr}$. If
 i is a singleton set i.e. $i \cdot \text{val} = 0$ then
 $\cdot \text{ptr}$ will point to itself and thus it will return
itself, which is true as per the definition of
the $\text{NextInit}()$. Now if i is not a singleton
set i.e. it is a part of some other bigger set
then its val must be equal to 1 as we perform
a union only when we set value of element to i .
So, $\text{find}(i)$ i.e. leader of i 's $\cdot \text{ptr}$ value will
point to the element of greater than equal to
index whose value is 0. Thus we return $\text{find}(i) \cdot \text{ptr}$
and so it makes the return definition of NextUnset as

①

init (9)

①²

• val = 0

• pt = 1

②²

• val = 0

• pt = 2

...

⑨²

• val = 0

• pt = 9

where ~~some~~ arrow represents the leader.

Is set (3)

will return 3. val which is 0

set(4)

temp = find(i+1) • pt. — ⑥ ⑤ ②

= find(5) • pt

= 5 • pt

= 5

// 5's leader and pt are both itself

i.val = 1

y.val = 1

// 4.val is updated to 1

⑥ ⑤ ②

④

val = 1

pt = 4

union(i+1, i)

union(5, 4)

// ⑤ and ④ are combined in one set {5, 4} where

leader is implementation dependent
• val and • pt remains unchanged

for each element in this step.

find(i) • pt = temp — ⑥ ⑤ ②

find(4) • pt ⇒

4's leader • pt will now have value of temp = 5

Next Unset (4)

it will return $\text{find}(i) \cdot \text{pts}$ as per (b) (iv) so,

$$\Rightarrow \text{find}(i) \cdot \text{pts}$$

$$\Rightarrow \text{leader}(4) \cdot \text{pts}$$

$$\Rightarrow 5 \quad (\text{as mentioned in the last step of } \text{set}(4))$$

Thus 5 is returned.

Set (5)

$$\text{temp} = \text{find}(i+1) \cdot \text{pts} \quad \text{---} \quad \text{(b)} \quad \text{(ii)} \quad \text{(a)}$$

$$= \text{find}(6) \cdot \text{pts}$$

$$= 6 \cdot \text{pts}$$

$$= 6 \quad // \quad 6's \text{ leader and pts are both itself}$$

$$i.val = 1 \quad \text{---} \quad \text{(b)} \quad \text{(ii)} \quad \text{(b)}$$

$$5.val = 1 \quad // \quad 5.val \text{ is updated to } 1 \quad \text{(5)}^2$$

$$i.val = 1$$

$$i.pts = 5$$

$$\text{Union}(i+1, i) \quad \text{---} \quad \text{(b)} \quad \text{(ii)} \quad \text{(c)}$$

$$\text{union}(6, 5) \quad // \quad 5 \text{ and } 6 \text{ are now combined to form one set. i.e. } \{4, 5, 6\}$$

are now combined into a single set.

$i.val = 2$ $i.pts$ in this step remains unchanged for each element.

$$\text{find}(i) \cdot \text{pts} = \text{temp} \quad \text{---} \quad \text{(b)} \quad \text{(ii)} \quad \text{(d)}$$

$\text{find}(5) \cdot \text{pts} \Rightarrow 5$, ~~pts~~ leader.pts will now have value of $\text{temp} = 6$
leader is implementation dependent 2 can be any one of the above 3 elements.

Next Unset(4)

It will return $\text{find}(i) \cdot \text{ptr}$ as per (b) (iv), so,

⇒ $\text{find}(4) \cdot \text{ptr}$

now 4 belongs to the set $\{4, 5, 6\}$

This set's leader ptr has a value of 6 as mentioned in the last ~~of~~ step of the last operation.

Thus 6 will be returned.

Set(7)

$\text{temp} = \text{find}(i+1) \cdot \text{ptr}$ — (b) (ii) (a)

$= \text{find}(8) \cdot \text{ptr}$

$= 8$ // 8's ptr and leader is itself.

$\text{f.val} = 1$ — (b) (ii) (b)

$\text{f.val} = 1$ // f.val is updated to 1

$\text{union}(i+1, i)$ — (b) (ii) (c)

$\text{union}(8, 7)$ // now 7 & 8 are combined in one set. leader is implementation dependent i.e. can be either of the two. $\text{val} = 2$. ptr of each element remains unchanged in this step.

$\text{find}(i) \cdot \text{ptr} = \text{temp}$ — (b) (ii) (d)

$\text{find}(7) \cdot \text{ptr}$ ⇒ leader of 7's set ptr will now have value temp = 8.

set(8)

temp = find(i+1).ptr — (b) (i) (a)

= find(9).ptr

= 9 // 9's ptr and ~~not~~ leader are itself.

i.val = 1 — (b) (i) (b)

8.val = 1 // 8.val is set to 1 now.

union(i+1, i) — (b) (i) (c)

union(9, 8) // now 9 & 8 are combined into one set. i.e. {7, 8, 9} are combined into one set as 7 & 8 were already a part of one set. val & ptr of each element remains unchanged in this step.

find(i).ptr = temp — (b) (i) (d)

find(8).ptr \Rightarrow leader of 8's set . ptr will now point to temp i.e. temp = 9.

leader is implementation dependant & thus can be any one of the 3 above elements.

isSet(4)

will return 4.val which is 1; updated in set(4) call.

Set(6)

temp = find(i+1) . pts — (b) (ii) (a)

⇒ find(7) . pts

⇒ 9 // 7 belongs to set {7, 8, 9}

whose leader . pts contains value of 9 as it mentioned in last step of set(8) call.

i.val = 1 — (b) (ii) (b)

6.val = 1 // 6.val is set to 1.

union(i+1, i) — (b) (ii) (c)

union(7, 6) // 7 & 6 are combined into one set. i.e. 7 belonged to set {7, 8, 9} and 6 belonged to set {4, 5, 6} thus these 2 sets are joined / combined into {4, 5, 6, 7, 8, 9} whose leader is implementation dependant. .val and .pts of each element remains unchanged in this step.

find(7) . pts = temp — (b) (ii) (d)

find(6) . pts ⇒ 6's set's leader which can be any one of the above element, .pts value i.e. leader . pts value will be temp which is 9

Next Unset (4)

it will return $\text{find}(i)$ - pts as per (b) (iv), so

2) $\text{find}(4)$ - pts.

now 4 belongs to the set $\{4, 5, 6, 7, 8, 9\}$ whose leader - pt has value of 9 (as mentioned in the last step of last function call).

Thus it will return 9.

(d) Time complexity.
